

Escrow Pay

Trade with strangers safely.

Mobile-first onchain escrow for in-person resale. Funds sit in a program-controlled account until the buyer releases them. No middleman holds the money — not even us.

CLOCK IN · Solana Mobile hackathon by RadiantsDAO
Flutter · Anchor / Rust · Solana devnet

THE PROBLEM

Someone always goes first.

In a face-to-face resale one side has to move before the other. The seller hands over and hopes payment lands; the buyer pays and hopes the goods are real. Bank transfers reverse, cash is a risk to carry, and a stranger’s screenshot proves nothing.

Buyer’s risk

Pay first and the seller can simply walk.

Seller’s risk

Hand over first and the payment may never clear.

Neither can verify

No shared record either side trusts.

Money and goods move together.

- 1

Seller lists

Item and price become a QR code. Nothing touches the chain yet.
- 2

Buyer scans and funds

One signature opens the escrow and deposits. Funds are held by the program.
- 3

Buyer inspects

A refund window runs. The buyer can still pull out.
- 4

Release at handover

The buyer shows a release code; the seller scans it and is paid on the spot.

Show the buyer

0.45 SOL

Pixel 8 Pro, 256GB

You receive

0.45 SOL

Paid to

Fg6P...sLnS

Reference

1790435254583

Refund window

1d

Network

devnet

Show this to the seller

Scanning it pays 0.45 SOL to Fg6Pa...FsLnS. This cannot be undone.

The code only ever pays the seller named above — it cannot be pointed anywhere else, so it is safe to show.

Copy link (if scanning won't work)

Hide

Rules, not promises.

● Neither party holds the funds

A program-derived account custodies the deposit. Not the seller, not the buyer, not us.

● The payout address is fixed

Set when the escrow opens. No instruction can redirect it, whoever submits one.

● Inaction has a deadline

A buyer who never confirms cannot strand the money. After the window the seller can claim.

● The release code is safe to show

It authorises a payment, never a destination — so a courier can scan it without being trusted.

WHAT WE BUILT

Native mobile, onchain settlement.

Onchain

- Anchor program, six instructions
- PDA per trade, 138-byte account
- Deployed and live on devnet

Mobile

- Flutter, Android, Mobile Wallet Adapter
- Camera QR scan and generation
- Deep links, share sheet, secure storage

Verified

- 37 onchain tests incl. abuse paths
- 105 app tests, analyzer clean
- Devnet smoke test on every deploy

What this does not solve.

A chain cannot know whether goods changed hands in a car park. No escrow can. What it can decide is who a stalemate favours, and what each side is able to do. We say so plainly rather than claiming otherwise.

Open today

- A buyer who takes the goods and refunds inside the window
- SOL only — USDC settlement is designed for, not built
- Android only, because Mobile Wallet Adapter is

Next

- An arbiter who can only pay buyer or seller — never a third address
- Photo and video evidence, hashed onchain
- Courier handover: the release code already supports any submitter
- USDC, and a longer window for faults found later

Escrow Pay

Trade with strangers safely.
